EJB as a Component

EJB as a component

EJBs are referring to the server-side components that you can use to build parts of your application such as the business logic or persistence code.The real idea behind a component is that it should effectively encapsulate application behaviour which can be reusable.

There are three types of EJB components:

- Session Beans
- Message-driven Beans
- Entity Beans

> Session beans and Message-driven beans are used to implement business logic in an EJB application, and entities are used for persistence.
